# Agenda

Motion with constant acceleration 

Freely falling objects 

Quiz time 

Quick recap

# All about motion

- Motion is everywhere (obvious and subtle)
- Motion is relative: an object relative to another
- Studying motion: kinematics is how, dynamics is why

$$\vec{F} = m\vec{a}$$

why  $\leftrightarrow$  how

# Displacement

- Position is where an object is at any particular time
- Distance traveled is the total length of the path traveled between two positions
- Displacement is the change in position:  $\Delta x = x_f - x_0$

# Velocity

- Time is in terms of change. Elapsed time is  $\Delta t = t_f - t_0$
- Average speed is total distance traveled divided by travel time, and is not the magnitude of average velocity
- Instantaneous speed is speed at an instant of time, and is the magnitude of instantaneous velocity
- (Average) velocity  $\bar{v}$  is displacement divided by travel time:  
$$\bar{v} = \frac{\Delta x}{\Delta t} = \frac{x_f - x_0}{t_f - t_0}$$
- Instantaneous velocity  $v$  is velocity at a specific instant:  
$$v = \lim_{\Delta t \rightarrow 0} \frac{\Delta x}{\Delta t} = \frac{dx}{dt}$$

# Acceleration

- (Average) acceleration  $\bar{a}$  is the rate at which velocity changes:  
$$\bar{a} = \frac{\Delta v}{\Delta t} = \frac{v_f - v_0}{t_f - t_0}$$
- Instantaneous acceleration  $a$  is the acceleration at a specific instant in time:  $a = \lim_{\Delta t \rightarrow 0} \frac{\Delta v}{\Delta t} = \frac{dv}{dt}$
- It is a vector so it can be caused by either a change in the magnitude or the direction of the velocity
- Deceleration is an acceleration in the opposite direction to an object's motion (velocity), causing it to slow down

## Oh dear, antelope!

*Example.* A cheetah is crouched 20 m to the east of a vehicle. At time  $t = 0$ , the cheetah begins to run due east toward an antelope that is 50 m to the east of the vehicle. During the first 2.0 s of the chase, the cheetah's  $x$ -coordinate varies with time according to the equation  $x = 20 \text{ m} + (5.0 \text{ m/s}^2)t^2$ .

- (a) Find the cheetah's displacement between  $t_1 = 1.0 \text{ s}$  and  $t_2 = 2.0 \text{ s}$ .
- (b) Find its average velocity during that interval.
- (c) Find its instantaneous velocity at  $t_1 = 1.0 \text{ s}$  by taking  $\Delta t = 0.1 \text{ s}$ , then  $0.01 \text{ s}$ , then  $0.001 \text{ s}$ .

## Quick recap

① Point axis in direction cheetah runs, so that all values will be positive.

② Place origin at vehicle.

③ Mark initial positions of cheetah and antelope.

④ Mark positions for cheetah at 1 s and 2 s.

⑤ Add the known and unknown quantities.

**Motion with constant acceleration** 

# Testing humans at high accelerations

In experiments carried out by the US Air Force in the 1940s and 1950s, humans riding a rocket sled could withstand accelerations as big as  $440 \text{ m/s}^2$ .

Photos 1-3 show Air Force physician John Stapp speeding up from rest to  $188 \text{ m/s}$  ( $678 \text{ km/h}$ ) in just 5 s.

# Kinematic equations

- When acceleration is constant, these **kinematic equations** relate the position  $x$  and velocity  $v$  at any time  $t$  to initial position  $x_0$ , initial velocity  $v_0$  (both measured at time  $t_0 = 0$ ), and acceleration  $a$

$$v = v_0 + at, \quad x = x_0 + v_0 t + \frac{1}{2}at^2, \quad v^2 = v_0^2 + 2a(x - x_0),$$

$$x - x_0 = \bar{v}t, \quad \bar{v} = \frac{1}{2}(v_0 + v),$$

## Motion with constant acceleration ○

- ▶ Again, we take acceleration to be constant so  $\bar{a} = a$  at all times, and initial time to be zero
- ▶ In vertical motion,  $y$  takes the place of  $x$

## Just motorcyclin'

*Example.* A motorcyclist heading east through a small town accelerates at a constant  $4.0 \text{ m/s}^2$  after he leaves the city limits. At time  $t = 0$ , he is  $5.0 \text{ m}$  east of the city-limits signpost while he moves east at  $15 \text{ m/s}$ . (a) Find his position and velocity at  $t = 2.0 \text{ s}$ . (b) Where is he when his speed is  $25 \text{ m/s}$ ?

## I am speed

*Example.* A motorist traveling at a constant  $15 \text{ m/s}$  ( $54 \text{ km/h}$ ) passes a school crossing where the speed limit is  $10 \text{ m/s}$  ( $36 \text{ km/h}$ ). Just as the motorist passes the school-crossing sign, a police officer on a motorcycle stopped there starts in pursuit with constant acceleration  $3.0 \text{ m/s}^2$ . (a) How much time elapses before the officer passes the motorist? At that time, (b) what is the officer's speed and (c) how far has each vehicle traveled?

# I am speed

(a)

Questions? 🤔

Freely falling objects 🍁

# Free fall

- An object in **free-fall** experiences constant acceleration if air resistance is negligible (here only gravity affects the motion)
- On earth, all free-falling objects have an acceleration  $a_g$  due to gravity, which averages at  $a_g = 9.8\text{m/s}^2$

# Free fall

- Acceleration  $a_g$  can be taken either as  $+a_g$  or  $-a_g$  depending on your choice of coordinate system. If you choose upward to be positive,  $a = -a_g$  is negative, otherwise  $a = a_g$ . Former is the typical choice
- Since  $a$  is constant in free-fall, you can use above kinematic equations where either  $a = \pm a_g$

## A freely falling coin

*Example.* A one-peso coin is dropped from the Leaning Tower of Pisa and falls freely from rest. What are its position and velocity after 1.0 s, 2.0 s, and 3.0 s? Ignore air resistance.

## A freely falling coin

*Example.* A one-peso coin is dropped from the Leaning Tower of Pisa and falls freely from rest. What are its position and velocity after 1.0 s, 2.0 s, and 3.0 s? Ignore air resistance.

Questions? 🤔

Quiz time 🕒

# I am speed: which $v$ - $t$ graph is correct? Why?

(a)

(a)

(b)

(c)

(d)
